As in ridge regression, selecting a good value of  $\lambda$  for the lasso is critical. One obvious advantage of lasso regression over ridge regression, is that it produces simpler and more interpretable models that incorporate only a reduced set of the predictors. However, neither ridge regression nor the lasso will universally dominate the other.

In statistics and machine learning, lasso is a regression analysis method that performs both variable selection and regularization in order to enhance the prediction accuracy and interpretability of the statistical model it produces. It was originally introduced in geophysics literature in 1986, and later independently rediscovered and popularized in 1996 by Robert Tibshirani, who coined the term and provided further insights into the observed performance. Lasso was originally formulated for lin

Lasso (statistics) - Wikipedia

Least absolute shrinkage and selection operator regression (usually just called lasso regression) is another regularized version of linear regression: just like peak regression, it adds a regularization term to the cost function. , but it uses the  $\ell_1$  norm of the weight vector instead of half the square of the  $\ell_2$  norm.

Ridge and Lasso Regression with Python

Lasso and Ridge regression applies a mathematical penalty on the predictor variables that are less important for explaining the variation in the response variable. This way, they enable us to focus on the strongest predictors for understanding how the response variable changes. This is referred to as variable selection.

Understanding Lasso and Ridge Regression | R-bloggers

The Variable Selection Property of the Lasso. The lasso and ridge regression coefficient estimates are given by the first point at which an ellipse contacts the constraint region. ridge regression: circular constraint with no sharp points, so the ridge regression coefficient estimates will be exclusively non-zero.

Study Note: Model Selection and Regularization (Ridge & Lasso)

Lasso (L1) and Ridge (L2) Regularization Regularization is a technique to discourage the complexity of the model. It does this by penalizing the loss function. This helps to solve the overfitting problem.

Lasso regression, or the Least Absolute Shrinkage and Selection Operator, is also a modification of linear regression. In Lasso, the loss function is modified to minimize the complexity of the model by limiting the sum of the absolute values of the model coefficients (also called the  $\ell_1$ -norm).

We will use the sklearn package in order to perform ridge regression and the lasso. The main functions in this package that we care about are Ridge (), which can be used to fit ridge regression models, and Lasso () which will fit lasso models. They also have cross-validated counterparts: RidgeCV () and LassoCV (). We'll use these a bit later.

12. Lasso regression. LASSO (Least Absolute Shrinkage Selector Operator), is quite similar to ridge, but lets understand the difference them by implementing it in our big mart problem. `from sklearn.linear_model import Lasso. lassoReg = Lasso(alpha=0.3, normalize=True)`  
`lassoReg.fit(x_train,y_train)` `pred = lassoReg.predict(x_cv)` # calculating mse

Lasso regression is also called as regularized linear regression. The idea is to induce the penalty against complexity by adding the regularization term such as that with increasing value of regularization parameter, the weights get reduced (and, hence penalty induced). The hypothesis or the mathematical model (equation) for Lasso regression is same as linear regression and can be expressed as the following. However, what is different is loss function. Fig 1. We will use the `glmnet` package in order to perform ridge regression and the lasso. The main function in this package is `glmnet ()`, which can be used to fit ridge regression models, lasso models, and more. This function has slightly different syntax from other model-fitting functions that we have encountered thus far in this book.

What is Ridge and Lasso Regression? -H2S Media

Lasso, or Least Absolute Shrinkage and Selection Operator, is quite similar conceptually to ridge regression. It also adds a penalty for non-zero coefficients, but unlike ridge regression which penalizes sum of squared coefficients (the so-called L2 penalty), lasso penalizes the sum of their absolute values (L1 penalty).

From what I know, using lasso for variable selection handles the problem of correlated inputs. Also, since it is equivalent to Least Angle Regression, it is not slow computationally. However, many people (for example people I know doing bio-statistics) still seem to favour stepwise or stagewise variable selection.
