Synthesis has the lowest use and depends on single threaded execution mostly so what you need is a machine with the largest cache (L3 or L4 if you can get it) you can get. Basically 4 core 8 thread cpus with large L3 cache and highest clock frequency are your best bet; for single build use.

The main difference between simulation and synthesis in VHDL is that simulation is used to verify the functionality of the circuit while synthesis is used to compile VHDL and map into an implementation technology such as FPGA. Generally, Hardware Description Language is a language that describes the functionalities of electronic circuits. These languages are different from regular programming languages.

Simulation is the process of using a simulation software (simulator) to verify the functional correctness of a digital design that is modeled using a HDL (hardware description language) like Verilog. Synthesis is a process in which a design behavior that is modeled using a HDL is translated into an implementation consisting of logic gates. This is done by a synthesis tool which is another software program.

Here, the focus is on hardware synthesis functions, called hardware metafunctions, which synthesize hardware in a provably correct manner. Designs produced using the metafunctions are correct-by-construction and are formally related to their specifications by simple substitution or rewriting of terms within the correctness theorem for each metafunction.
